DecisionRL: Enhancing Decision Calibration through Reinforcement Learning

Reinforcement Learning Course Project Proposal

Team Members: • Taihua Chen (260010020) • Yanyun LIU (260010215)

Research Question

As large language models evolve from question answerers to decision makers, efficient and reliable decision-making becomes increasingly important. While System 2-style models emphasize deliberate, multi-step reasoning, System 1-style models aim to provide fast, intuitive judgments. Jev introduces a complementary paradigm of structured probabilistic decisions, producing explicit probability distributions over candidate actions instead of lengthy reasoning trajectories. Inspired by this paradigm, our project explores how **Reinforcement Learning for Calibrated Decisions (RLCD)** can enhance decision accuracy, probability calibration, and reliability through a reproducible training framework.

Related Work

Jev introduces System 1-style probabilistic decision-making and RLCD, while **Microsoft-Decision-1** demonstrates the potential of efficient decision models. However, their proprietary implementations and limited disclosure of training methodologies restrict reproducibility. **Clef** provides open model weights but does not offer a fully reproducible training pipeline. Meanwhile, **Laya** and **Kev** provide open-source implementations of typed-decision models. Laya introduces a practical RLCD training approach, whereas Kev primarily adopts supervised learning and post-hoc calibration. However, RLCD optimization remains relatively underexplored, particularly in reward design and policy optimization. Our project aims to develop a reproducible RLCD training framework and explore improvements in reinforcement learning strategies.

Planned Approach

We plan to develop **DecisionRL** by exploring decision model design and reinforcement learning strategies for reliable and calibrated decision-making. This development will involve two main components: data construction and curation, and model training with RLCD optimization.

- **Data Construction and Curation.** We plan to collect diverse datasets across multiple domains to support model training and evaluation. We will develop a data processing pipeline for data acquisition, cleaning, and augmentation. Hard-labeled data will be used to establish the model's foundational classification capabilities, while soft-labeled data will support RLCD training to better calibrate predicted probabilities.
- **Model Training and RLCD Optimization.** Using **EuroBERT** as our base checkpoint, we will adopt a two-stage training framework. First, we will perform supervised fine-tuning (SFT) on high-quality decision datasets to establish general decision-making capabilities. We will then apply RLCD to optimize decision probabilities using verified probabilistic supervision. We also aim to improve Laya's original RLCD algorithm by exploring enhanced reinforcement learning optimization strategies for more reliable and calibrated decisions.

Evaluation Plan

We will evaluate DecisionRL on hard-label benchmarks (e.g. Banking77) and soft-label benchmarks (e.g. Typed Decisions), comparing it with representative decision models (e.g. Jev). The evaluation will use **Accuracy**, **Macro F1 Score**, **Expected Calibration Error**, and **Brier Score** to assess the foundational decision-making capabilities established through SFT, with particular emphasis on analyzing how RLCD and our proposed improvements affect probability calibration and decision-making behavior.

Required Resources and Division of Responsibilities

Resources: No additional equipment or specialized resources are required.

Preliminary Division of Responsibilities: Both team members will jointly participate in project discussions, research planning, and RLCD methodological design. Yanyun LIU will primarily contribute to data collection, synthesis, and quality control, while Taihua Chen will focus more on model and algorithm optimization.
